# Conclusions

- Reduced Dynamic (RD) are more accurate than the dynamic DORIS orbits, however...
- RD orbit centering is less stable than that of the dynamic orbit, and is much more sensitive to systematic XY error in the TRF. Changes to the RD empirical acceleration span of 28 min (1/4 rev) may affect this sensitivity. Both orbits sensitive to TRF error in Z.
- Results suggest the dynamic orbits are perhaps better centered about the Earth's CoM, and not the origin of the particular station network polyhedron assumed for each orbit solution.
- SLR+DORIS RD orbit centering appears a little more stable than DORIS - only.
