**PRE-GRACE era recovery of time-varying  
DORIS-based mass concentration  
parameters for TOPEX/Poseidon precise  
orbit determination**

J. Moyard, F. Mercier, A. Couhert from CNES POD Team

# SUMMARY

## CONFIGURATION

## PRELIMINARY VALIDATION

## TOPEX/Poseidon orbits performance

## CONCLUSION

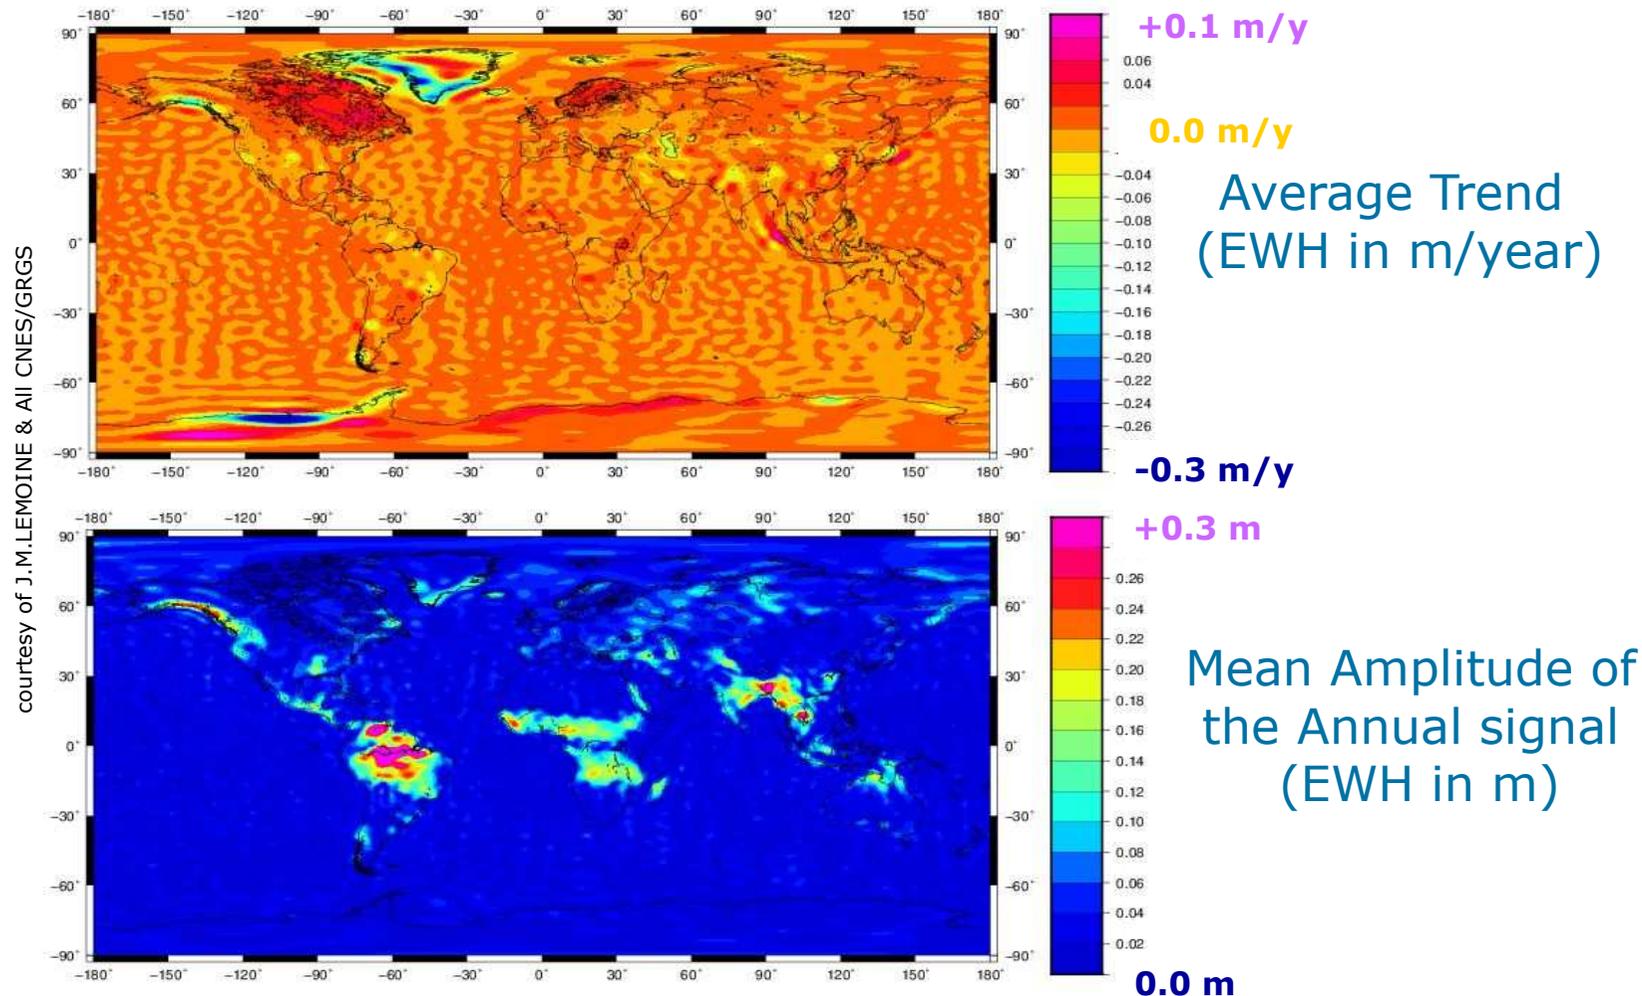

# DEFINITION

Localization of mascons need some information on variable masses location, i.e. long term or periodic signals

*GRACE times series CNES/GRGS, 2002 → 2016*

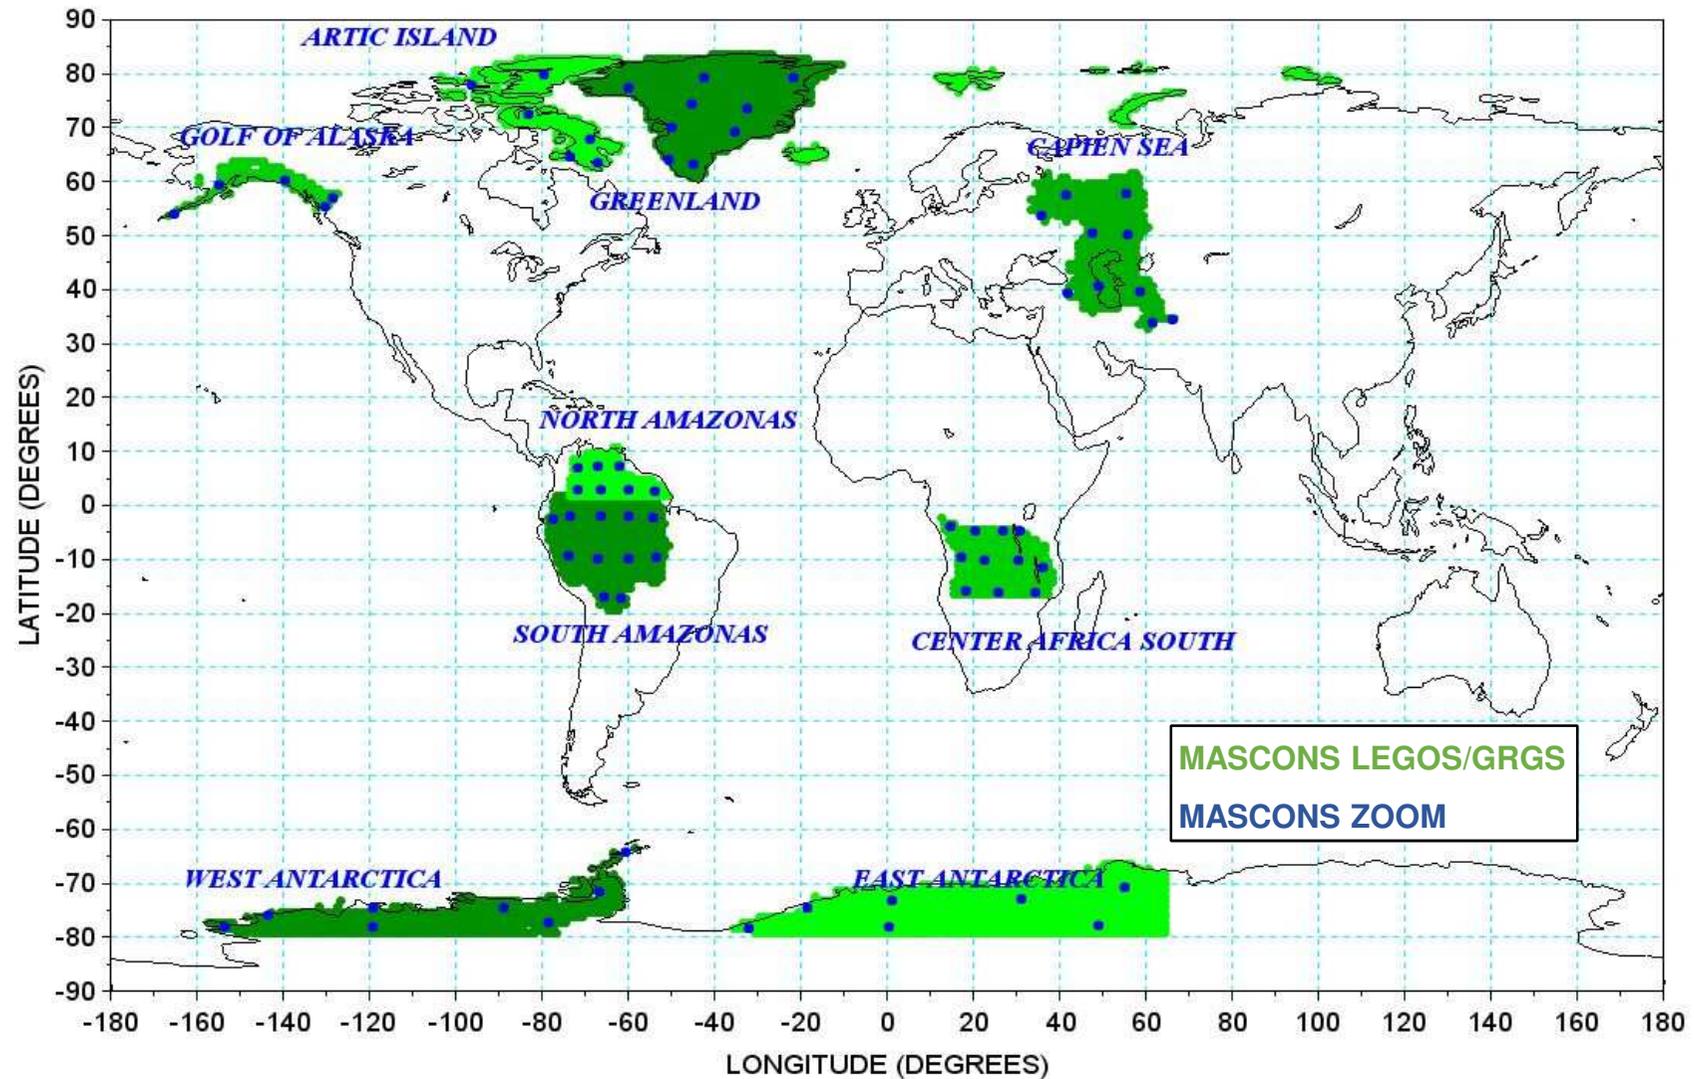

# DEFINITION

## MASCONS TOPOLOGY, 9 regions

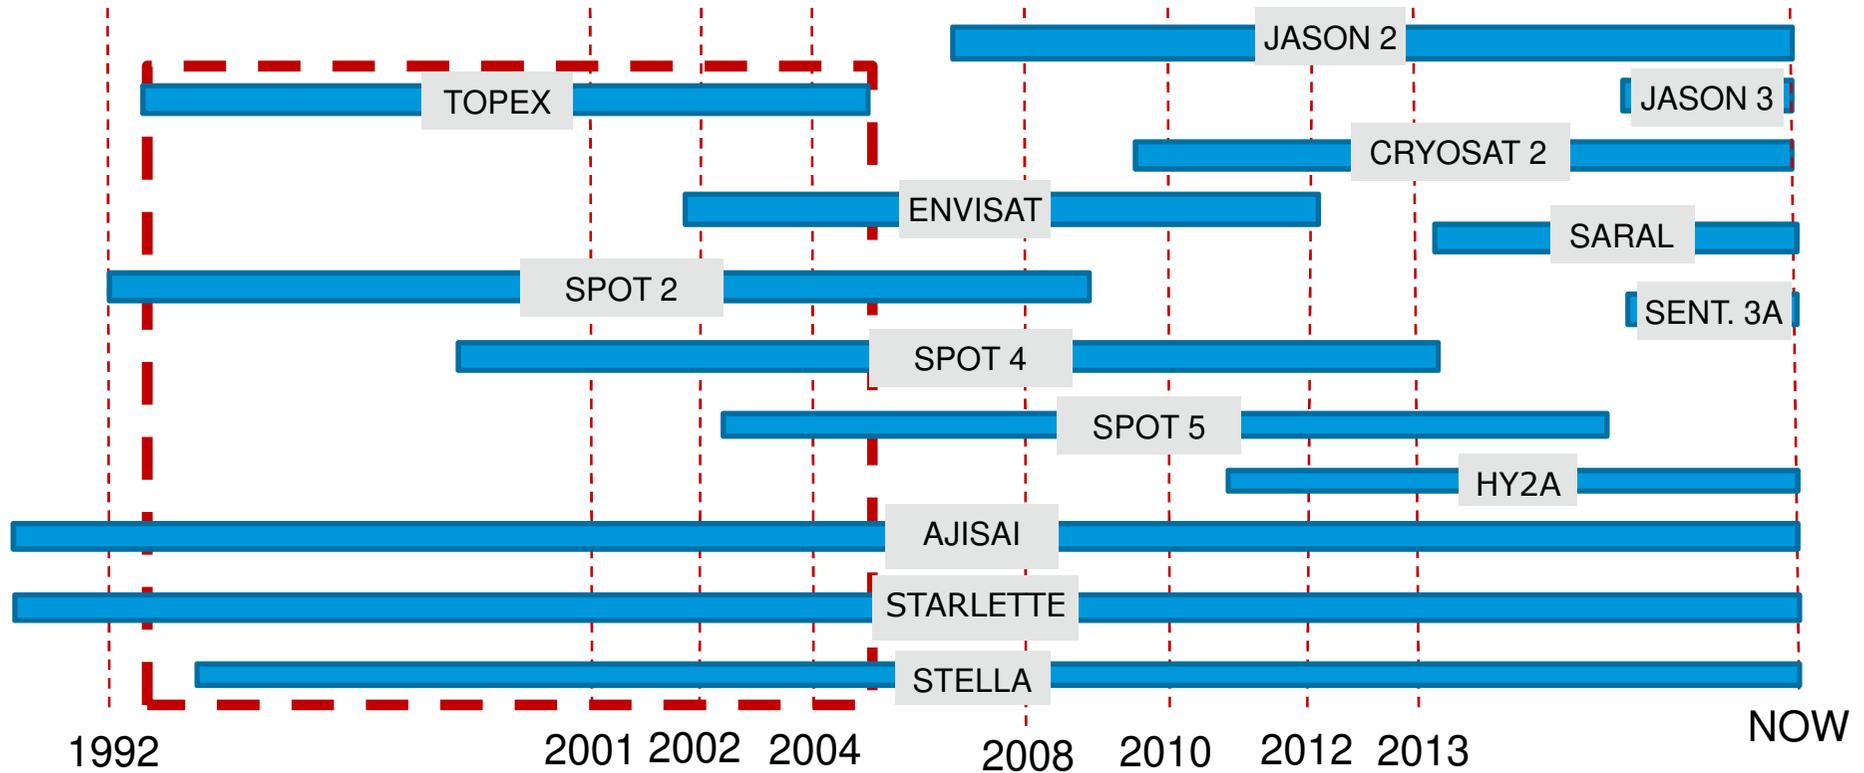

# DEFINITION

## 14 MISSIONS, 11 DORIS and 3 SLR

Orbit determination process uses only DORIS measurements ( $\sigma=0.5\text{cm}$ ) or SLR measurements ( $\sigma=2.0\text{cm}$ )

Normal equations stacking process includes noise model correlated to mascons latitude

TOPEX period, stacking process :

starts with 2 missions “DORIS” and 3 missions “SLR”

ends with 5 missions “DORIS” and 3 missions “SLR”

# PRELIMINARY VALIDATION

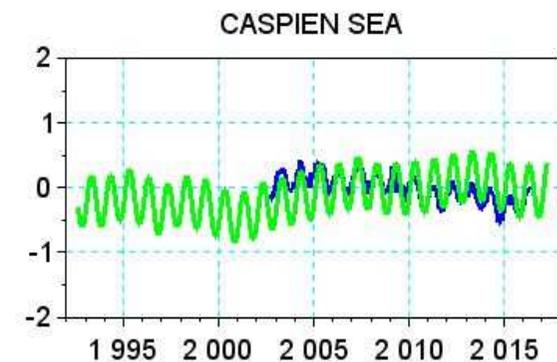

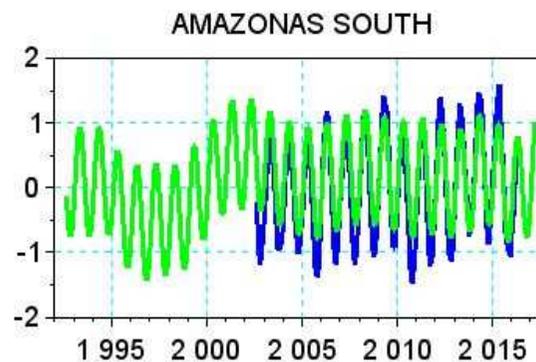

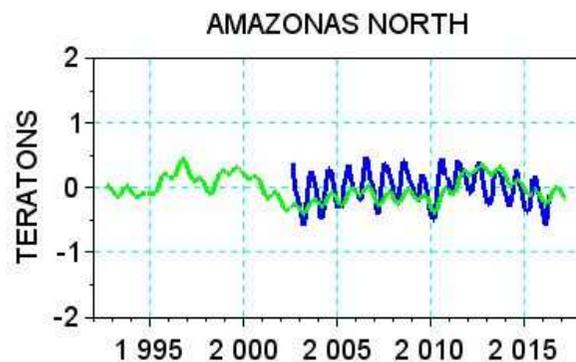

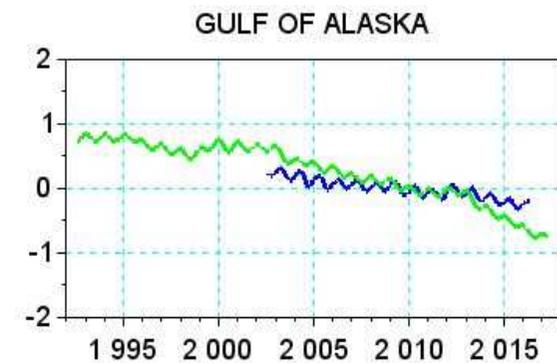

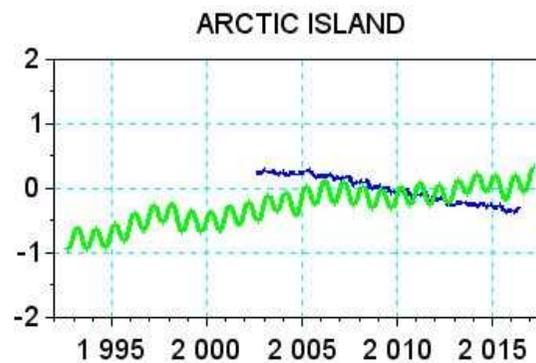

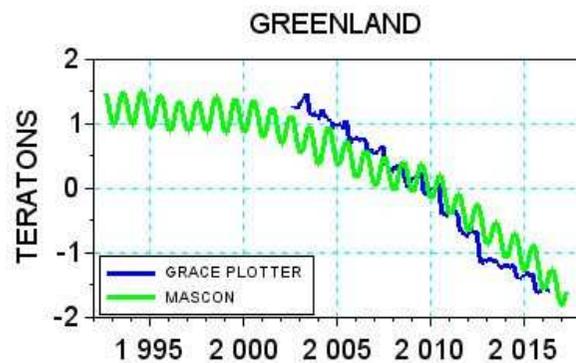

Comparison with GRACE PLOTTER tool → [www.thegraceplotter.com](http://www.thegraceplotter.com)

CNES/GRGS static field used in orbit determination process to estimate mascons

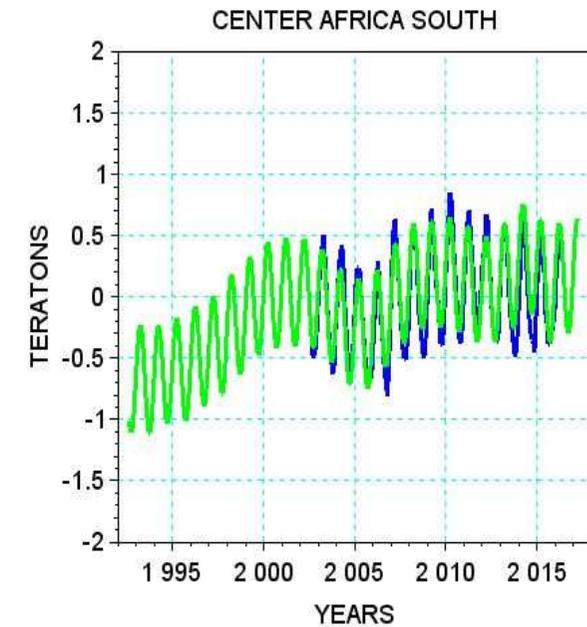

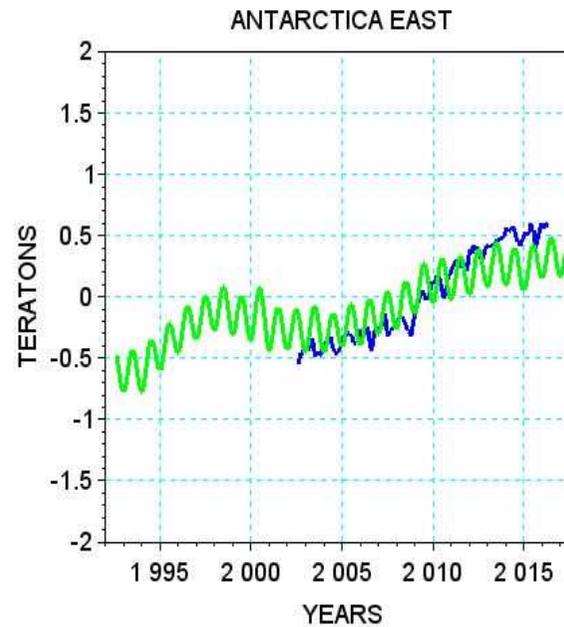

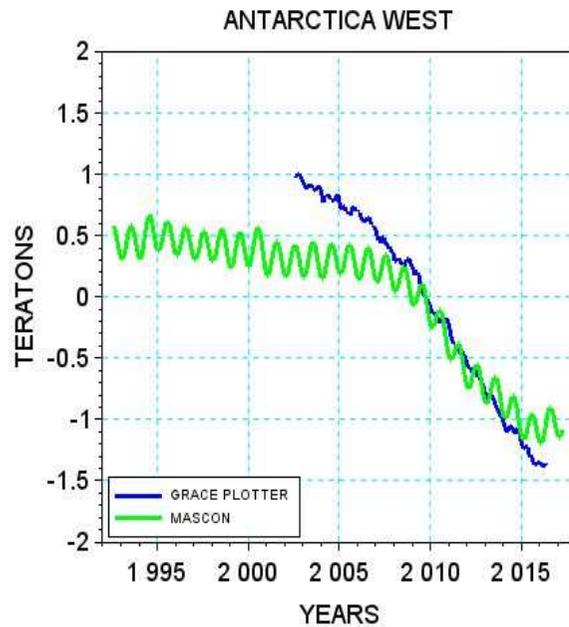

+ GDR-E POE CNES standard

+ stacking process on 3 months

# PRELIMINARY VALIDATION

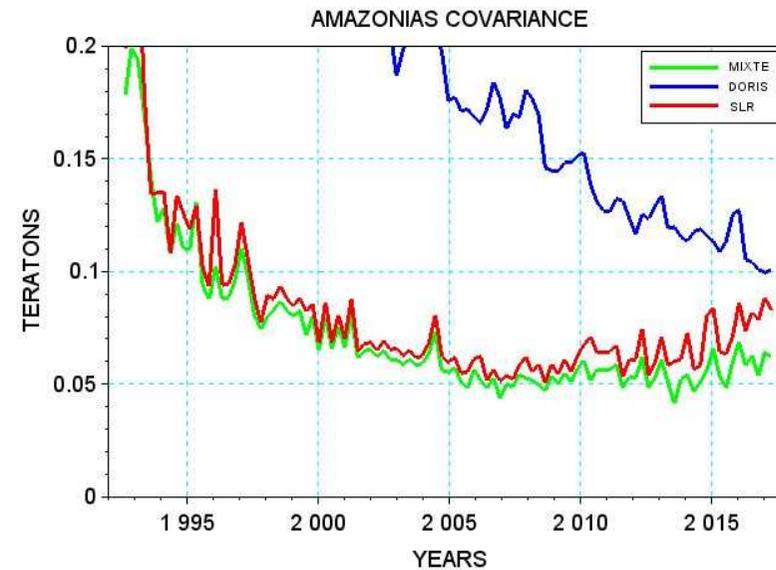

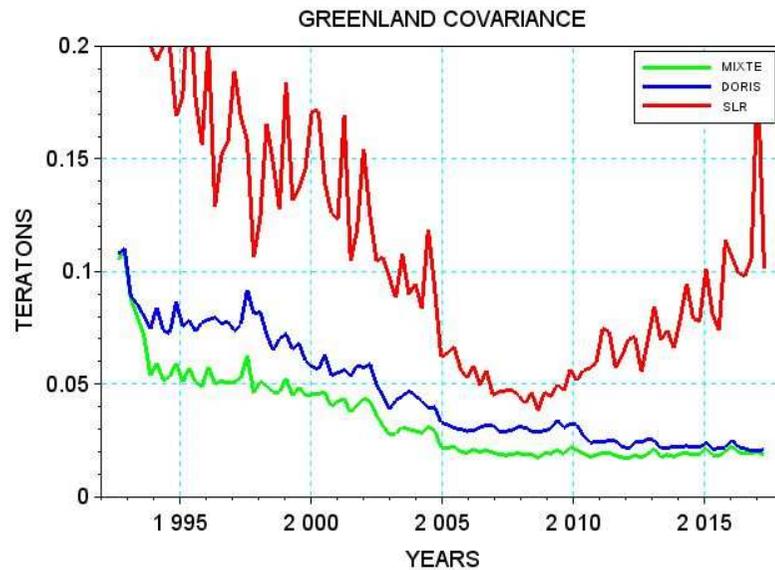

Except for Artic Island, behaviour of other 8 mascons seems quite good in regards of GRACE PLOTTER data

# PRELIMINARY VALIDATION

Equivalent covariance for all except for Amazonias regions

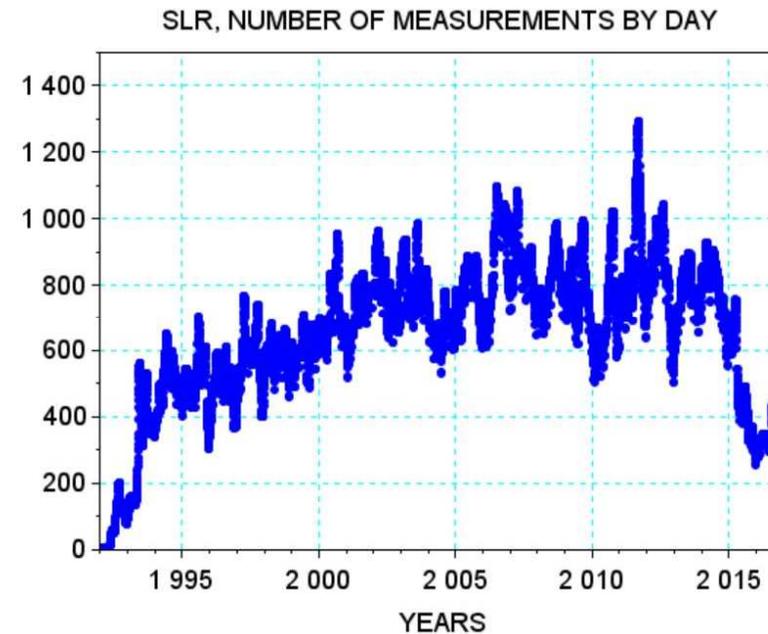

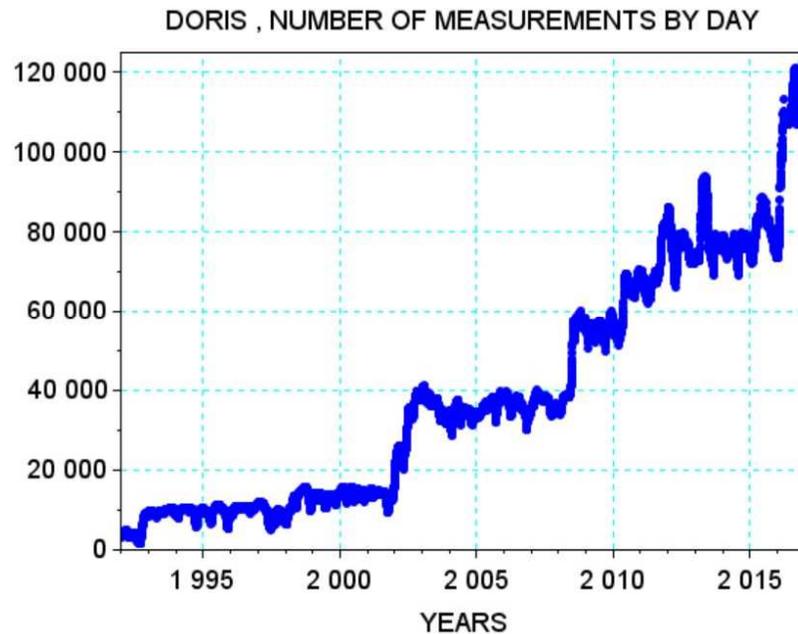

Covariance « mixte solution » for Amazonias has an amplitude x 2 in comparison to others mascons covariance

# PRELIMINARY VALIDATION

A comparison of the covariance DORIS/SLR plots could be done with number of measurements for each solution

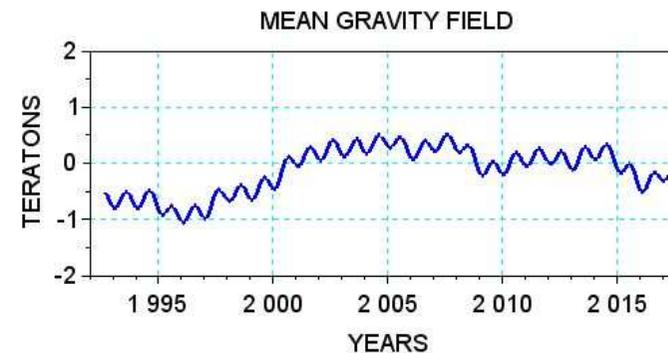

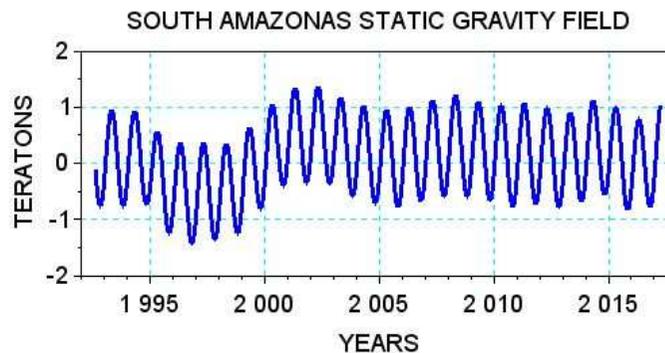

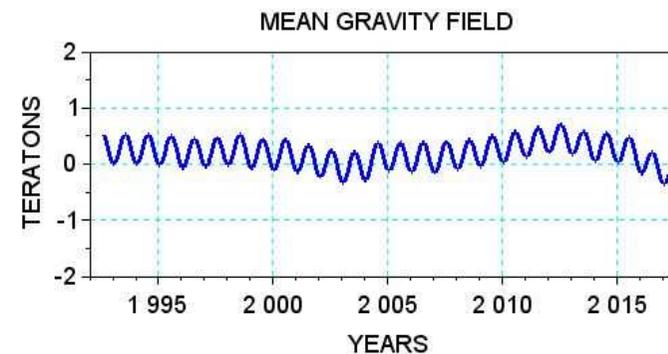

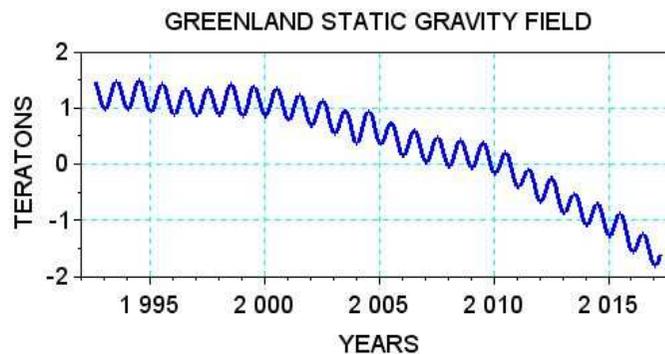

# PRELIMINARY VALIDATION

Comparisons between mascons estimated with static field vs mascons estimated with mean field.

<https://grace.obs-mip.fr/> : *mean field contains a series of periodic and secular gravity variations for the lowest degrees of gravity field. Those variations include annual, semi annual and drift terms*

→ if a mascon(mean field) values are around 0. on GRACE period, a good observation to validate this mascon on pre-GRACE period

# TOPEX POSEIDON Orbits performance

CNES/GRGS mean field used in orbit determination process.

(for degree 2 of mean field, TVG are extended to 1985-2012 using LAGEOS/LAGEOS2 SLR mission)

GDR-E POE CNES standard

Confident in annual and semi-annual periodic terms of mean field, focus on drift/bias

Normal equations stacking process on five years, focus on long term

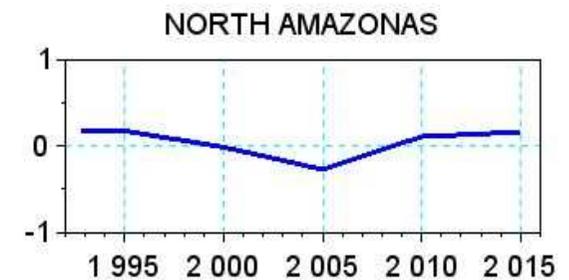

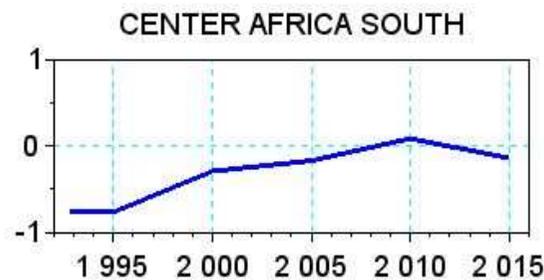

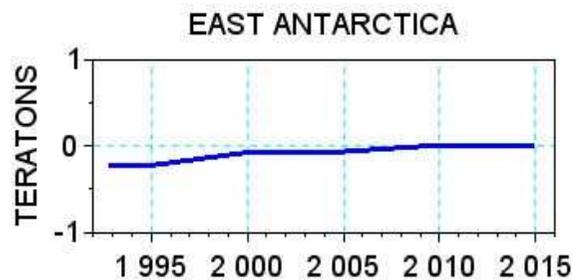

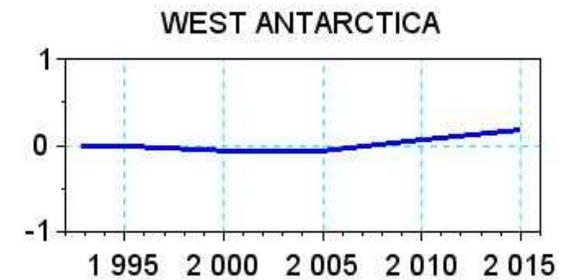

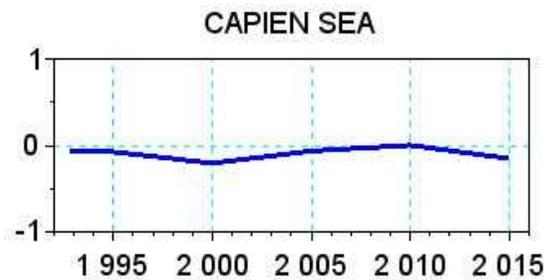

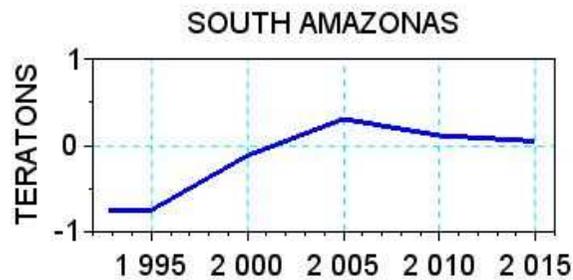

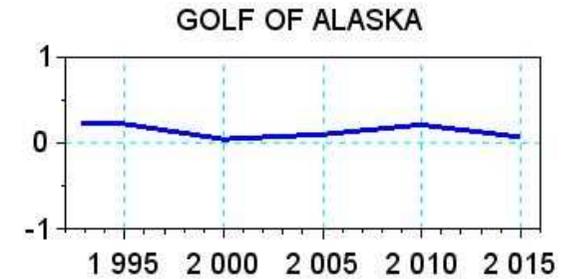

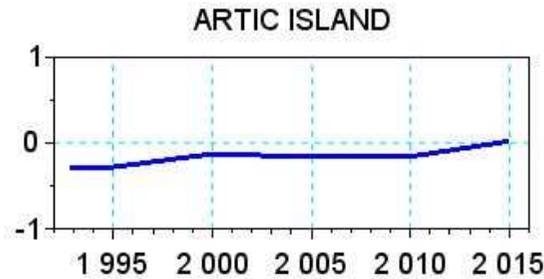

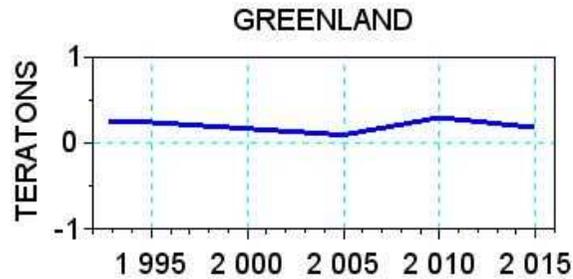

Impact on Orbits performance criteria ( RMS SLR + Crossover Variance ) on period pre-GRACE ?

# TOPEX POSEIDON Orbits performance

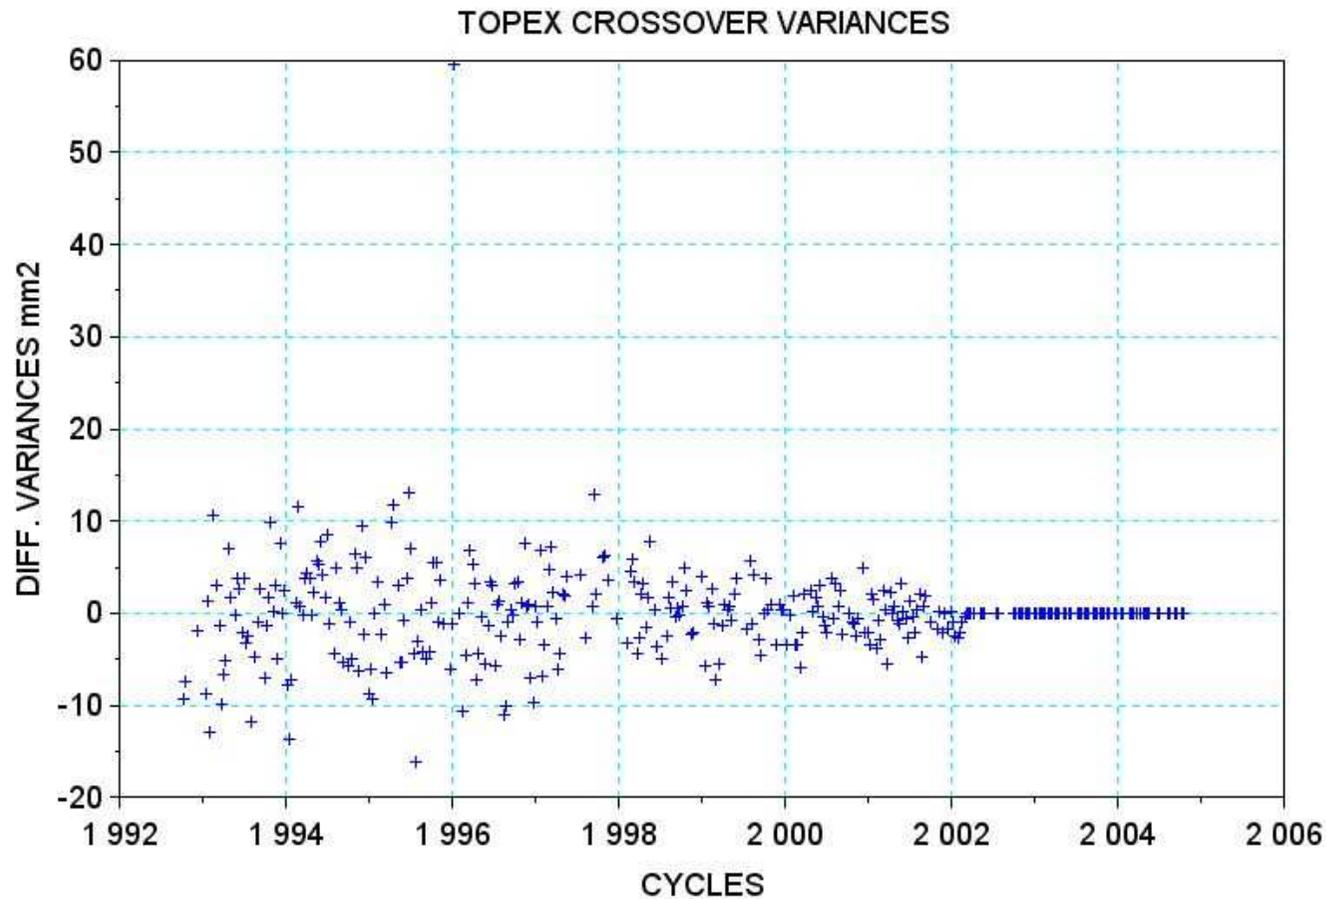

## Adjusted mascons

CROSSOVER VARIANCE between GDR-E vs GDR-E+mascons  
mean  $0.026\text{mm}^2$  / median  $0.002\text{mm}^2$

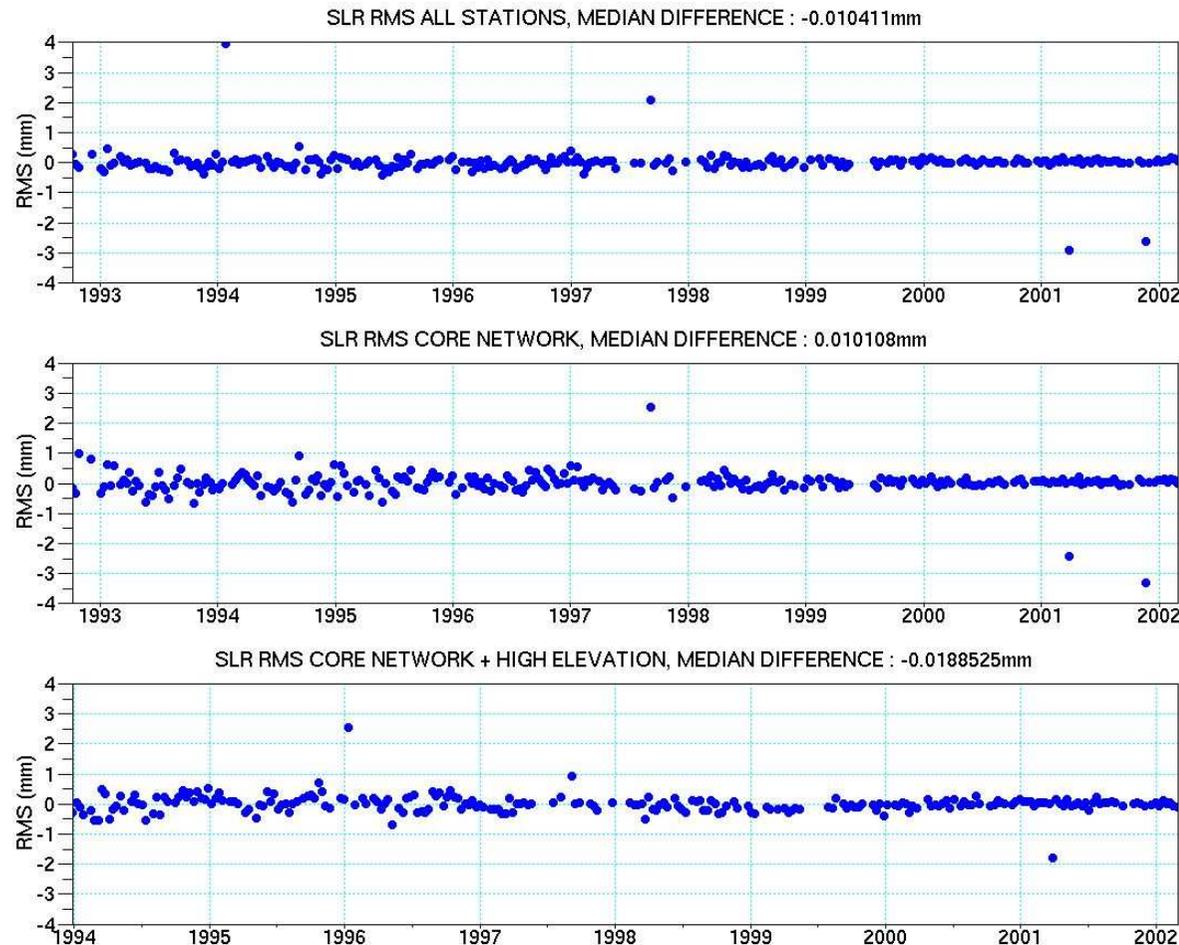

no improvement for this criteria...

# TOPEX POSEIDON Orbits performance

## SLR RMS between GDR-E vs GDR-E+mascons

no improvement  
for this criteria  
too...

For CNES/GRGS mean field, extension of TVG to 1985-2012 using LAGEOS/LAGEOS2 SLR mission is efficient for orbits TOPEX performance

# CONCLUSION

MASCONS approach give good results in comparison with GRACE PLOTTER tools (physical point of view) : give an insight on the mass evolution of Greenland before the GRACE era

Some tested regions need to be improved in our approach like Artic Islands

For CNES/GRGS mean field, extension of TVG to 1985-2012 using LAGEOS/LAGEOS2 SLR mission could be enough for orbits TOPEX performance, mascons approach doesn't give real improvement yet.

Mascons approach could be improved :

9 mascons are not enough to cover all regions with long term or periodic signals, could add more mascons but observability issue to be solved ?

Improved models like troposphere (test GPT GMF1 instead of GPT GMF) in DORIS orbit dermination or cut off à 20° (annual period amplitude)

# THANK YOU FOR YOUR ATTENTION QUESTIONS ?

# PRELIMINARY VALIDATION

Comparisons between mascons estimated with static field vs mascons estimated with mean field, not very clean on Amazonia mascons
